**Abstract:**

The subject of this thesis is to measure spatial variations of electromagnetic fields from circular time varying current sources. In order to verify experimental measurements digital computer models of the fields in free space were derived. Fields within Ringer's solution contained within cylindrical and rectangular boundaries were measured experimentally. It was found that neither boundary provides for uniform field magnitudes throughout the containers regardless of the direction of the applied magnetic field from the circular current loops. A coaxial cylindrical container was suggested as a means of providing more uniform fields throughout the solution.

A brief Fourier analysis of several types of waveforms induced in the Ringer's solution was also performed.

## STATEMENT OF PERMISSION TO COPY

In presenting this thesis in partial fulfillment of the requirements for an advanced degree at Montana State University, I agree that the Library shall make it freely available for inspection. I further agree that permission for extensive copying of this thesis for scholarly purposes may be granted by my major professor, or, in his absence, by the Director of Libraries. It is understood that any copying or publication of this thesis for financial gain shall not be allowed without my written permission.

## ACKNOWLEDGMENTS

The author extends appreciation and thanks to Dr. A. A. Pilla and Electro-Biology Inc. for the use of the BI-OSTEOGEM. The author would also like to thank Dr. Daniel March and Dr. Donald Pierre for their suggestions in the preparation of this paper. The author is especially grateful for Dr. Bruce R. McLeod's support, suggestions and encouragement throughout the project. Most of all the author is thankful for the support given from his wife and his parents.

## ABSTRACT

The subject of this thesis is to measure spatial variations of electromagnetic fields from circular time varying current sources. In order to verify experimental measurements digital computer models of the fields in free space were derived. Fields within Ringer's solution contained within cylindrical and rectangular boundaries were measured experimentally. It was found that neither boundary provides for uniform field magnitudes throughout the containers regardless of the direction of the applied magnetic field from the circular current loops. A coaxial cylindrical container was suggested as a means of providing more uniform fields throughout the solution.

A brief Fourier analysis of several types of waveforms induced in the Ringer's solution was also performed.

## INTRODUCTION

Electromagnetic energy has been shown to be a catalyst to certain functions of selected biological systems. These catalytic properties are now being used clinically to heal recalcitrant bone fractures. Several researchers have conducted numerous experiments testing the effects of electromagnetic energy on biological systems [1,2,3]. Some systems Dr. A. A. Pilla has tested include: calcium uptake in embryonic chick tibia [4], modulation of rat radial osteotomy repair (with P. Christel and G. Cerf)[5], and lifespan extension (electromagnetic energy in addition to chemotherapy for positive results, with Dr. Steve Smith) of rats with melanomas [6]. Because Pilla used induced energy as opposed to dc delivered by metal conductors, the possibility of a chemical reaction between the system and the apparatus used to apply energy is eliminated.

Certain experiments of Pilla's have shown that slight changes in waveforms applied to biological systems produce dramatically different results. For example, by changing only the repetition rate of a five msec, burst type waveform, percent change versus controls vary from slightly negative to largely positive [5]. Although some Fourier analysis was done in order to determine an approximate upper frequency limit of the spectral components of the waveform, it did not become clear why different waveforms caused different results.

When cells are exposed to induced energy the question arises: are all cells throughout the system exposed to the same magnitudes of  $\vec{E}$ , the electric field intensity vector, as well as  $\vec{H}$ , the magnetic field intensity vector? Obtaining boundary conditions such that all cells of the system are exposed to uniform magnitude  $\vec{E}$  and  $\vec{H}$  could contribute to the study of biological response versus magnitudes of the induced fields. Further, Gandhi [7] has indi-

cated that the direction of a propagating wave could be significant in regards to biological effects. Thus, perhaps knowledge of direction of the fields with respect to individual cells could be important.

The main contribution of this thesis is to study field patterns in homogeneous material within various boundary conditions. Rectangular and cylindrical containers were considered as boundaries for Ringer's solution and electric field patterns within the containers were determined experimentally for different directions of the applied time varying magnetic field. Although not considered in this thesis theoretical models of electric field intensity within the rectangular containers have been derived by Dr. Bruce R. McLeod [8]. Because biological cells introduce a boundary not considered in any measurements or derivations in this thesis, the values of the fields and currents within the cell were not determined. However, this thesis will show that cells at various positions of the system will certainly be exposed to different magnitudes of external currents and fields and the degree of variation of the exposure depends upon position as well as orientation of the biological system.

## Chapter I

### SPATIAL VARIATIONS OF ELECTRIC AND MAGNETIC FIELDS IN FREE SPACE

#### Theoretical Fields for Circular Current Loops

In order to obtain theoretical models for  $\bar{E}$  and  $\bar{B}$ , the electric field intensity and magnetic field density vectors respectively, it is appropriate to begin with Maxwell's second equation

$$\nabla \cdot \bar{B} = 0 \quad (1)$$

From Equation 1 through the use of a vector identity it can be shown that

$$\bar{B} = \nabla \times \bar{A} \quad (2)$$

The direction of the applied field and low back EMF dictate that only the phi ( $\phi$ ) component of  $\bar{A}$  exists, where phi is the direction shown in Figure 1. From symmetry  $\partial/\partial\phi = 0$  so it follows that

$$\nabla \cdot \bar{A} = 0 \quad (3)$$

for cylindrical coordinates. Thus, Equations 2 and 3 totally define the vector  $\bar{A}$ . From Maxwell's third equation,

$$\nabla \times \bar{E} = - \partial\bar{B}/\partial t \quad (4)$$

with the use of Equation 1 and the vector identity, the curl of the gradient of any scalar is identically zero, Equation 5 results

$$\bar{E} = - \nabla V - \partial\bar{A}/\partial t \quad (5)$$

Since  $-\nabla V$  is the solution to the homogeneous form of Equation 4, the solution for  $\bar{E}$  with  $\partial I(t)/\partial t$  as well as  $\partial\bar{B}/\partial t$  equal to zero, must be  $-\nabla V$ . However, since  $\rho = 0$ , i.e., no

free charge density between the coils as well as at the source, it follows that  $V = 0$ .

Therefore,

$$\vec{E} = -\partial\vec{A}/\partial t \quad (6)$$

The two equations used to determine spatial variations of field quantities in free space, with a circular current loop the source, have been derived as follows [9,10] :

$$A_\phi = \frac{\mu I}{k} \left(\frac{a}{r}\right)^{1/2} [(1 - \frac{1}{2}k^2)K - E] \quad (7)$$

$$B_z = \frac{\mu I}{2} \frac{1}{[(a+r)^2 + z^2]^{1/2}} \left[ K + \left(\frac{a^2 - r^2 - z^2}{(a-r)^2 + z^2}\right)E \right] \quad (8)$$

Where:  $I$  and  $a$  is the current and fixed radius respectively of the loop;  $k^2 = 4ar / [(a+r)^2 + z^2]$ ;  $\mu$  is the permeability constant;  $K$  and  $E$  are elliptic integrals of the first and second kinds respectively, and  $z$  and  $r$  are the running variables of the coordinate system as shown in Figure 1.

It is noted that both of the references cited for Equations 7 and 8 derived them for constant currents. However, they still hold for  $I$  replaced by  $I(t)$ , a time varying current. Also, an equation for the radial component of the magnetic field density vector  $B_r$  was given by the references cited. Since  $B_r$  was found to be nearly an order of magnitude smaller than  $B_z$  in the region of constant  $B_z$ ,  $B_r$  was ignored.

In order to obtain theoretical free space values of  $B_z$  and  $E_\phi$  versus position, Equations 7 and 8 were programmed into a digital computer. Since the system was assumed linear, the principle of superposition was used to calculate relative field variations for a fixed  $z$  plane versus  $r$ . Once the magnitudes of the field quantities were obtained for two single turn current loops of specific dimensions, scale factors were applied for our case to obtain Figures 6 and 8. The multiplying factors included: the number of turns per coil of the

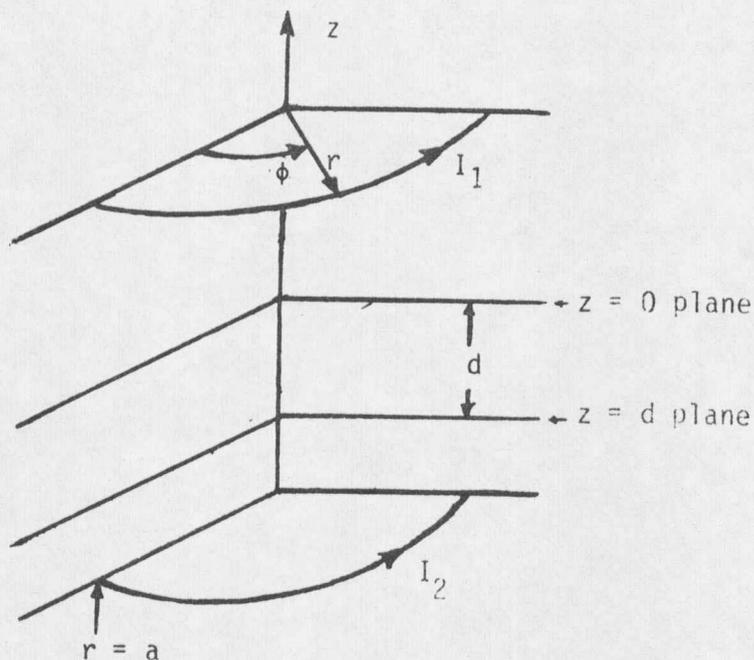

Fig. 1. Coordinate System.

driving coil system (DCS) and the value of the  $\partial I(t)/\partial t$  and  $I(t)$  at some specific time ( $t_1$ ) for  $E_\phi$  and  $B_z$  respectively. Methods used to determine  $I(t)$  and  $\partial I(t)/\partial t$  are shown in Appendix D. Also, included in the program (FIELDS) was a subroutine to evaluate elliptic integrals [11]; the program is displayed in Appendix A.

#### Selection Inductive Test Systems

In order to verify the theoretical equations for  $E_\phi$  and  $B_z$ , a method of measurement had to be devised. This section explains the theory used to choose the inductive test systems (ITS's) used to gather data.

The coupling of  $\bar{E}$  and  $\bar{B}$ , as seen in Equation 4, creates the possibility of calculating  $\bar{E}$  and  $\bar{B}$  as functions of  $r$  and  $z$  from measurements of the same quantity. From Equation 4 using Stoke's theorem it follows that

$$\oint \bar{E} \cdot d\bar{l} = - \int \frac{\partial \bar{B}}{\partial t} \cdot d\bar{s} = \partial \Phi / \partial t \quad (9)$$

Equation 9 is equal to the induced electromotive force (EMF). However, the different differentials of the two integrals make it convenient to have a separate source of EMF for  $\bar{E}$  and  $\bar{B}$  determinations. Thus, in order to verify plots obtained theoretically, different sources of EMF were used for  $\bar{E}$  and  $\bar{B}$ .

Although  $\bar{E}$  varies with  $r$ ,  $z$  and time it does not vary with  $\phi$ ; also, only a  $\phi$  component of  $\bar{E}$  exists. Therefore, since

$$d\bar{l} = r d\phi \bar{a}_\phi \quad (10)$$

and since  $E_\phi$  is a constant of integration in Equation 9 a measured EMF with a proper device allows  $E_\phi$  to be calculated for a particular radius in a constant  $z$  plane.

Unfortunately, since  $B_z$  varies with respect to  $r$ ,  $B_z$  is not a constant of integration. However, assuming the theoretical plots to be correct (Figures 6 and 8),  $B_z$  is nearly constant for the range of  $r$  from zero to four centimeters. Therefore,  $B_z$  was assumed constant with respect to integration in that range and a suitable differential is

$$d\bar{s} = r' dr' d\phi' \bar{a}_z \quad (11)$$

Primed variables indicate that the center of the  $d\bar{s}$  did not necessarily coincide with the center of the coordinate system of the DCS as shown in Figure 2.
