Terrorism and political attitudes: Evidence from European social surveys

Giovanni Peri, Daniel I. Rees, Brock Smith

1. Introduction

Terror attacks in Western Europe have been trending upwards since the mid-2000s, with a notable spike in the years 2014 and 2015 (Fig. 1). There were, for instance, an average of 70 terror attacks per year in Western Europe during the period 2004–2007 as compared to an average of 239 attacks per year during the period 2015–2018. Many observers have argued that the recent surge in terrorism has increased anti-immigrant sentiment among Europeans and increased support for right-wing parties and politicians (Smale and Castle 2016; Fekete 2018; Roth 2018; Turak 2018).

In this study, we explore the effects of terror attacks in Europe on political attitudes and orientation. Drawing on data from the European Social Survey (ESS) for the period 2002–2018, our focus is on terror attacks that caused at least one fatality and, importantly, occurred when the ESS was in the field. Every two years, a new round of the ESS is conducted. The ESS interviews residents of more than 20 countries across Europe on a wide range of topics, including their attitudes towards immigration, the degree to which they trust the institutions of government, their satisfaction with the current national government, and their political orientation on a left-right scale. Because we know the exact date each interview started, we can compare within-country responses to the ESS in the weeks before and after terror attacks, effectively accounting for the influences of economic conditions and other difficult-to-observe factors that could potentially bias naïve estimates.

Previous quasi-experimental studies on terror attacks in Europe and political attitudes have produced decidedly mixed results. For instance, Finseraas et al. (2011) found that Europeans became more supportive of imposing restrictive immigration policies immediately after the murder of Dutch film-maker Theo van Gogh by a member of a radical Islamist group, while Silva (2018) found little evidence to suggest that attitudes towards immigrants among Europeans shifted in the aftermath of the Charlie Hebdo shootings. With the exception of Akay et al. (2020), previous quasi-experimental studies estimating the effects of terror attacks in Europe on political attitudes and orientation have focused on a single event or country, limiting their generalizability and raising questions about external validity.

We begin our empirical analysis by examining ESS interviews conducted during the two weeks leading up to fatal terror attacks and the two weeks after. Identification is based on 16 pre-versus post-attack comparisons in 9 different countries (the Czech Republic, France, Germany, Ireland, the Netherlands, Poland, Spain, Sweden, and the United Kingdom). Next, we adopt a 4-week bandwidth, which effectively means that identification is based on 12 pre-versus post-attack comparisons in 6 countries (France, Germany, the Netherlands, Spain, Sweden, and the United Kingdom).

We find little support for the hypothesis that terror attacks in Europe...
influenced attitudes towards immigration or political orientation: using either a two- or 4-week bandwidth, the estimated effect of terror attacks are generally small and statistically insignificant at conventional levels. By contrast, we observe sizeable post-attack increases in satisfaction with the national government and trust in parliament, but only among respondents living in the region of the country that was attacked and only when using a 4-week bandwidth. These post-attack increases in satisfaction with the national government and trust in parliament are consistent with “rally-around-the-flag effects” documented by political scientists (Mueller 1973; MacKuen 1983; Brody and Shapiro 1989; Brody 1991).

Our results complement and extend those of Akay et al. (2020). Using data from Germany, the United Kingdom, and Switzerland for the period 1994–2013, these authors found a strong positive association between terror attacks and conservative voting intentions. However, because of data limitations, they did not consider other outcomes having to do with political orientation or opinions. If terror attacks do, in fact, lead to more conservative voting intentions, then our results suggest that this effect does not reflect increased animosity towards immigrants, nor does it necessarily mean that there was a rightward shift in political orientation.

The remainder of this study is organized as follows. We briefly review the quasi-experimental literature in the next section. In Section 3, we describe our data and methodology. In Section 4, report our principal results. Estimates at the regional level are reported in Section 5 and estimates for specific country-round pairs (e.g., estimates based on the responses of French participants immediately before and after the Charlie Hebdo shootings, which occurred while Round 7 of the ESS was in the field) are reported in Section 6. Section 7 concludes.

2. Background

2.1. Potential mechanisms

Group-threat theory is often used by academics to explain why terror attacks and economic contractions might increase support for right-wing political parties and contribute to anti-immigrant sentiment (Balogh 1967; Quillian 1995; Legewie 2013; Lindén et al., 2018; Vasilopoulos et al., 2019). According to group-threat theory, negative sentiment towards an “outgroup” (for instance, members of a racial/ethnic minority or immigrants from non-European countries) increases when the dominant group feels that its privileges and position are being threatened.

---

Notes: This figure shows the total number of terror attacks and the number of fatal terror attacks occurring in countries that participated in the European Social Survey, excluding Israel, Turkey and Russia. Data on terror attacks comes from the Global Terrorism Database (GTD) and pertain to the period 2000-2018.

Fig. 1. Terror Attack Trends in Western Europe, 2000-2018

Notes: This figure shows the total number of terror attacks and the number of fatal terror attacks occurring in countries that participated in the European Social Survey, excluding Israel, Turkey and Russia. Data on terror attacks comes from the Global Terrorism Database (GTD) and pertain to the period 2000-2018.
threatened (Blumer 1958; Quillian 1995).2

Political scientists have also observed that terror attacks can, under certain circumstances, have rally-around-the-flag effects, which refer to a rise in popular support for the national government or leaders following a crisis. According to Mueller (1973), rally-around-the-flag effects can be thought of as a “patriotic reflex” among both elites and non-elites in response to a sudden and dramatic crisis affecting the entire nation. Brody and Shapiro (1989) and Brody (1991) argue that rally-around-the-flag effects are more likely to occur when there is a lack of publicly available information about the nature of the crisis, obliging the opposition to withhold criticism. There is evidence that, if the terror attack is especially destructive, the rally-around-the-flag effect can be long-lasting. President George W. Bush’s sustained surge in approval ratings following the 9/11 attacks is perhaps the most notable example of a long-lasting rally-around-the flag effect (Chowanietz 2011).

2.2. Previous quasi-experimental estimates

Terror attacks are, by definition, designed to serve political ends (Thornton 1964; Kydd and Walter 2006), but their effectiveness is still being debated by researchers. Using data from opinion polls conducted in the lead up to parliamentary elections, Gould and Klor (2010) found that terror attacks increased Israelis’ willingness to grant territorial concessions to the Palestinians as part of a peace agreement. Gould and Klor (2010) also examined whether respondents intended to support the “right-wing bloc” in the upcoming elections. Consistent with the results of Akay et al. (2020), they found that terror attacks were associated with a rightward shift in the preferences of Israeli voters.3

Gassebner et al. (2008) and Balcells and Torrats-Espinosa (2018) examined whether incumbents or challengers benefited from terror attacks but came to opposite conclusions. After analyzing more than 800 elections taking place in 115 countries across the world, Gassebner et al. (2008) found “strong evidence that terrorist attacks increase the probability that the cabinet will be replaced after an election” (p. 129). By contrast, Balcells and Torrats-Espinosa (2018) found that attacks carried out by Euskadi Ta Askatasuna (ETA), a Basque terrorist organization, had no discernible impact on self-reported support for the incumbent party. Perhaps because they occurred just three days before an election, the 2004 Madrid train bombings have received a fair amount of attention from past researchers. Bali (2007) and Montalvo (2011, 2012) found that the bombings significantly contributed to the opposition party’s victory over the incumbent party, while Lago and Montero (2006) concluded that the bombings “have not changed the electoral preferences of Spaniards” (p. 22).

Silva (2018), who used data from the Round 7 of the ESS, found little evidence that the Charlie Hebdo shootings in 2015 shifted French attitudes (or attitudes in other European countries) towards immigrants and refugees. By contrast, Finseraa et al. (2011) found that ESS respondents across Europe became more supportive of imposing restrictive immigration policies immediately after the murder of Dutch film-maker Theo van Gogh by a member of a radical Islamist group in 2004. Several studies have examined the effects of the Paris attacks that occurred on November 13, 2015 (Nussio et al., 2019; Ferrín et al., 2020; Van Hauwaert and Huber 2020). Neither Nussio et al. (2019) nor Van Hauwaert and Huber (2020) found that French attitudes towards immigrants shifted in the wake of these attacks, while Ferrín et al. (2020) found that these attacks negatively affected attitudes towards immigrants among Europeans.4 Finally, Böhme et al. (2020) used data from the Eurobarometer Survey on 29 European countries for the period 2003–2017 to examine the association between terror attacks and the “public mood toward immigration salience” (Böhme et al., 2020, p. 442). These authors found a positive association between terror attacks and the percentage of respondents who indicated that immigration was one of the two most important issues facing their country.5

3. Data and methods

3.1. Data on terror attacks

Data on terror attacks come from the Global Terrorism Database (GTD), which is housed at the National Consortium for the Study of Terrorism and Responses to Terrorism (START). These data are based on a wide variety of publicly available sources, including newspaper and journal articles, legal documents, and other existing datasets.6 They contain detailed information on each attack, including the date in which it occurred, its location, the number of casualties, and the responsible group. The GTD data have been used by dozens of researchers interested in exploring the causes and consequences of terrorism.7

The GTD defines a terror attack as “aimed at attaining a political, economic, religious, or social goal.” Furthermore, there must be evidence that the attack was intended to coerce or send a message to a broad audience (as opposed to the immediate victims). Finally, terror attacks are, according to the GTD, perpetrated by a non-state actor (or actors) and are therefore distinct from “legitimate” warfare activities conducted by national governments or military forces.

Fig. 1 shows the number of terror attacks on European soil per year

---

2 Blumer (1958, p. 4), who pioneered group-threat theory, described racial prejudice as stemming from “a fear or apprehension that the subordinate racial group is threatening, or will threaten, the position of the dominant group”.2

3 See also Kibris (2011), Larsen et al. (2020), and Nussio (2020). Kibris (2011) examined the effects terror attacks carried out by the PKK (i.e., the Kurdistan Workers’ Party) on the 1991 and 1995 Turkish general elections. She found a strong positive association between casualties suffered by security forces and the vote share of right-wing parties. Larsen et al. (2020) found that Germans’ attitudes towards the European Union improved after the 2016 Berlin Christmas Market attack, while Nussio (2020) found that this same attack had no effect on Germans’ trust in government, national identification, and views of Islam.

4 Ferrín et al. (2020) used data on residents of 28 countries from the Eurobarometer survey. Consistent with the results of Nussio et al. (2019) and Van Hauwaert and Huber (2020), Ferrín et al. (2020) found no evidence that these attacks affected attitudes towards immigrants among French Eurobarometer respondents. Jakobsson and Blom (2014) found that attitudes towards immigrants became more positive after the Oslo terror attacks committed by Anders Behring Breivik in 2011.

5 See Godefroid (forthcoming) for a meta-analysis of 325 studies examining the association between terrorism and political attitudes, most of which were correlational (as opposed to quasi-experimental). She finds that terror attacks are associated with “small” increases in outgroup hostility and political conservatism. However, she cautions that these associations “vary widely” depending upon the methodology used, where the terror attack took place, and the perpetrator. Although Godefroid (forthcoming) includes studies of terror attacks that took place in Europe, she does not provide separate estimates of the association between terrorism and European political attitudes. See Finseraa and Listhaug (2013) and Legewie (2013) for quasi-experimental evidence on the relationship between terror attacks occurring outside of Europe on European attitudes towards immigrants and refugees. Finseraa and Listhaug (2013) examined the effects of the 2008 terror attacks in Mumbai, India using data from Round 4 of the ESS. Although Europeans were more fearful of terrorism after the attacks, there was no significant effect on support for liberal immigration policies. Legewie (2013) examined the effects of the 2002 terrorist bombing in Bali, Indonesia on attitudes towards immigrants, which occurred while the ESS was in the field in 9 European countries. He found that attitudes towards immigrants deteriorated significantly in Finland, Poland and Portugal.

6 START is a research center at the University of Maryland, College Park. It is dedicated to examining and understanding the causes and consequences of terrorism. See https://www.start.umd.edu/gtd for more information on collection methods and the information available in the GTD data.

7 See, for example, Choi (2010), Drakos (2010), Galbulloev and Sandler (2011), Findley and Young (2012), and Ding et al. (2017).
for the period 2000–2018. Since the mid-2000s, terror attacks have been trending upward, with a notable spike in 2014 and 2015 thought to be, at least in part, inspired by the rise of the Islamic State of Iraq and the Levant (ISIL) (Nesser et al., 2016). The number of fatal attacks, defined as attacks involving at least one death, are also shown in Fig. 1. After averaging fewer than 8 per year during the period 2004–2013, terror attacks involving at least one death peaked in 2014, when there were 233.

3.2. Measuring political attitudes and orientation

To explore the within-country effects of fatal terror attacks on political attitudes and orientation among Europeans, we use data from the European Social Survey (ESS). The ESS was launched in 2002. Since then, more than 430,000 respondents from 38 countries have been interviewed in person and asked a battery of questions about their attitudes, behaviors, and values. The ESS is a repeated cross-sectional survey that is conducted every two years, although there are changes to the mix of participating countries across rounds. It is considered to be a “model for international surveys” (Jagodzinski and Moschner 2008, p. 475) and has been used by previous researchers interested in estimating the various effects of terrorism (Finseraas and Listhaug 2013; Arvanitidis et al., 2016; Ahern 2018; Silva 2018). The ESS strives for an overall 70 percent response rate, although the non-response rate is higher than 30 percent in several countries. We use post-stratification weights available from the ESS to correct for any differences in response rates.

Our immigration-related outcomes are based on responses to two ESS questions. Specifically, the ESS asks respondents whether immigrants make their country “a worse or better place to live,” and how many immigrants from “poorer countries outside Europe” should be allowed in their country. Answers to the first question are on a 0–10 scale (where 0 is “worse place to live” and 10 is “better place to live”), while answers to the second question are on a 0–4 scale (where 0 is “allow many to come and live here” and 4 is “allow none”).

To gauge whether terror attacks affect attitudes towards government institutions, we use responses to three more ESS questions. Specifically, ESS respondents are asked how much trust they “personally” have in their country’s parliament and how much trust they have in the European Parliament. Answers to these questions are on a 0–10 scale, where 0 is “no trust at all” and 10 is “complete trust”. The ESS also asks respondents whether they are satisfied with the national government. Answers to this question are on a 0–10 scale, where 0 is “extremely dissatisfied” and 10 is “extremely satisfied”.

Finally, political orientation is based on how ESS respondents placed themselves on a 0–10 left-right political scale, where 0 means the far left and 10 means the far right. Previous studies using ESS data and this outcome include Thorisdottir et al. (2008), Piurko et al. (2011), and Aspelund et al. (2013). Descriptive statistics for all of the outcomes used in our analysis are provided in Appendix Table A1.

3.3. Empirical approach

We begin by restricting our attention to ESS interviews conducted during the two weeks leading up to a fatal terror attack and the two weeks after. Only ESS respondents from countries that were attacked are included in our analysis. Following Depetriz-Chauvin et al. (2020), we report ordinary least squares (OLS) estimates of the following equation:

\[ y_{icmt} = \beta_0 + \beta_{Post\_Attack}k_{icmt} + \theta_m + \delta_c + \epsilon_{icmt}. \]  

where \( y_{icmt} \) is one of several outcomes discussed above, \( i \) indexes respondents, \( c \) indexes country, \( m \) indexes calendar month (i.e., January–December), \( t \) indexes ESS rounds, and \( X \) represents a set of individual-level characteristics. The independent variable of interest is \( Post\_Attack \), equal to 1 if respondent \( i \) was interviewed after a fatal terror attack occurred and equal to 0 otherwise. Its coefficient, \( \beta_{Post\_Attack} \), measures the change in political attitudes from the pre-attack period (1–14 days before an attack) to the post-attack period (0–13 days after an attack).

If there were multiple attacks in country \( c \) during round \( t \), then the pre-attack period is based on the date of the first attack while the post-attack period is based on the date of the last attack.

Month fixed effects (\( \theta_m \)) account for any seasonality in political attitudes. Country-by-round fixed effects (\( \delta_c \)) ensure that identification comes from comparing within-country responses from interviews conducted shortly before and after attacks. The identifying assumption is that, conditional on \( X \), the timing of each interview was quasi-random, unrelated to the attack or unobserved characteristics of the respondent being interviewed. Regressions are weighted by the post-stratification weights provided by the ESS to correct for differences in selection probabilities. Standard errors clustered at the country-round level to allow for correlation of unobservable individual characteristics within a country-round.

Appendix Table A2 contains descriptions of the terror attacks used in our analysis, when they occurred, and the pre-versus post-attack periods. Identification is based on 16 pre-versus post-attack within-country comparisons. Five of these 16 comparisons involve multiple attacks (in France, Germany, Spain, and the United Kingdom), and remainder are based on a single attack (in the Czech Republic, France, Ireland, the Netherlands, Poland, Spain, Sweden, and the United Kingdom). Country-round pairs were included in the analysis only if ESS interviews were interviewed shortly before and after attacks. The identifying assumption is that, conditional on \( X \), the timing of each interview was quasi-random, unrelated to the attack or unobserved characteristics of the respondent being interviewed. Regressions are weighted by the post-stratification weights provided by the ESS to correct for differences in selection probabilities. Standard errors clustered at the country-round level to allow for correlation of unobservable individual characteristics within a country-round.

---

8 Non-fatal attacks were either aimed at property or were unsuccessful attacks with human targets.
9 Appendix B shows these questions as they appear on the survey.
10 We include the question about the European Parliament because the European Union is a frequent target of nationalist and anti-immigration politicians.

11 The Post_Attack indicator is equal to 1 if the interview was conducted on the day of the attack, but it is not clear whether ESS interviews were in fact conducted after the attack occurred. We have run an alternative specification where same-day interviews are dropped from the analysis and the results are qualitatively unchanged. These results are available upon request.

12 For example, there were two fatal terror attacks on German soil when Round 8 of the ESS was in the field. The first of these occurred on October 16, 2016, and the second occurred on December 19, 2016. Using a two-week bandwidth, our sample includes respondents interviewed 1–14 days before the attack on October 16 and those interviewed 0–13 days after the attack on December 19. Respondents interviewed between these two attacks are not included in the analysis. To take another example, there were 5 fatal terror attacks on French soil when Round 7 of the ESS was in the field. The first of these attacks occurred on December 20, 2014, and the last occurred on January 9, 2015. Using a two-week bandwidth, our sample includes respondents interviewed 1–14 days before the attack on December 20 and those interviewed 0–13 days after the attack on January 9. Appendix Figures A1 and A2 report interview counts in the pre- and post-treatment periods for each of the 16 country-round pairs that comprise the two-week bandwidth sample.
were conducted in each of the two weeks leading up to the first attack and each of the two weeks after the last. Five country-round pairs in which a fatal terror attack occurred while the ESS was in the field were excluded from our analysis because interviews were not conducted in each of the two weeks leading up to an attack and each of the two weeks after the attack.\(^\text{13}\)

### 3.4. Respondent characteristics and balance tests

Descriptive statistics for ESS respondent characteristics are provided in Panel An of Table 1. Following Muñoz et al. (2020), we conduct a balance test for several of these characteristics (age, gender, educational attainment, whether the respondent lives in an urban setting, minority status, and whether the respondent was “coping with their current level of income”) that, in theory, could be correlated with the outcomes under study.\(^\text{14}\) The results of regressing each of these characteristics on the post-attack dummy and country-by-round fixed effects are reported in the third column of Table 1 (Panel A). They suggest that the pre-versus post-attack samples are generally balanced, although two differences are statistically significant: experiencing a terror attack is associated with a 0.035 increase in the probability that the respondent lived in an urban area (compared to a mean of 0.627) and a 0.016 increase in the probability that the respondent self-identified as belonging to a minority group (compared to a mean of 0.047). Because it is possible that these associations are driven by post-attack concerns regarding ESS participation, we are careful to include a vector of individual-level characteristics, \(X\), in our regressions.\(^\text{15}\)

### 4. Main results

Estimates of \(a_1\) from equation (1) are reported in Panel An of Table 2. They provide little evidence that terror attacks influence political attitudes or orientation in Europe: without exception, the estimates of \(a_1\) are small and statistically insignificant at conventional levels. For instance, experiencing a fatal terror attack is associated with a (statistically insignificant) 0.093 increase (on a 0–10 scale) in whether respondents believed that immigrants made their country a better place, which is only 1.8 percent of the mean (5.188) and 4.0 percent of the standard deviation (2.277). The confidence 95% confidence interval for this estimate is –0.135 to 0.322, allowing to easily reject the hypothesis that fatal terror attacks had economically or socially meaningful effects. The other estimated coefficients reported in Panel An of Table 1 are smaller both in absolute value and relative to the mean and standard deviation.\(^\text{16}\)

In Panel B of Table 2, we examine ESS interviews conducted during the 4 weeks leading up to fatal terror attacks and the 4 weeks after, allowing for the possibility that the effects of terror attacks take more than two weeks to manifest. With a 4-week bandwidth, the pre-attack period is 1–28 days before the first terror attack while the post-attack period is 27 days after the last attack. In Panel B, the analysis is restricted to observations used in any of the 6 regressions reported in Panel An of Table 2. \(^\text{16}\)

\(^{15}\) It is also possible that experiencing a terror attack is correlated with difficult-to-measure (i.e., unobservable) attributes of respondents. An ESS manual posted online instructs interviewers to make 4 contact attempts over a two-week period. Respondents who worked longer hours held systematically different beliefs about politics and government institutions, then the regression results reported below could be biased. While this is an important caveat, we experimented with restricting our sample to pre-attack interviews and, with this restriction in place, found no evidence that interview dates were systematically related to our outcome variables.\(^\text{16}\)

In Appendix Table A3, we re-estimate equation (1) omitting the individual-level characteristics as controls. The results of this exercise are broadly consistent with those reported in Panel An of Table 2.
period is 0–27 days after the last. Because we require that ESS interviews were conducted in each of the 4 weeks leading up to the first attack and each of the 4 weeks after the last terror attack, identification is now based on 12 (as opposed to 16) pre-versus post-attack comparisons in 6 countries: France, Germany, the Netherlands, Spain, Sweden, and the United Kingdom. The estimates of $a_1$ reported in Panel B of Table 2 remain small and statistically insignificant at conventional levels.

Next, we explore whether the effects of terror attacks on political attitudes and orientation evolved over time using the 4-week bandwidth and a modified version of equation (1) in which the post-attack indicator is replaced with a series of mutually exclusive lead and lag indicators, allowing us to check for pre-treatment trends. Estimates for whether immigrants make the respondent’s country a better place to live are reported in Fig. 2. There is no evidence of pre-treatment trends (the estimated coefficients of the pre-event dummies are consistently small and statistically insignificant at conventional levels). One week after treatment, there is a modest 0.098 increase in how this question was answered, followed by a gradual decline of roughly equal magnitude,

but none of the post-treatment coefficients are sufficiently precise to reject the hypothesis of zero effect.

The event-study estimates for our other outcomes are reported in Figs. 3–7. In general, these estimates are small and statistically insignificant, but there is evidence of reduced satisfaction with the national government two to 3 weeks after an attack (Fig. 5). To explore whether this reduction in satisfaction with the national government persists, we widened the bandwidth from 4 to 8 weeks. The results of this exercise, which are reported in Appendix Figure A6, provide no evidence of a sustained reduction in satisfaction with the national government in the post-attack period.

5. Regional effects of terror attacks

Up to this point in the analysis, we have estimated average effects across ESS respondents living in country $c$, the country that was attacked. However, it is possible that attacks are more salient when they occur in the respondent’s own region of residence. ESS Rounds 4–9 provide “Nomenclature of Territorial Units for Statistics” (NUTS-1), which allow us to match where an attack occurred with each

Four of these 12 comparisons involve multiple attacks (in France, Germany, Spain, and the United Kingdom), and remainder are based on a single attack (in France, the Netherlands, Spain, Sweden, and the United Kingdom). Country-round pairs were included in the 4-week bandwidth analyses only if ESS interviews were conducted in each of the 4 weeks leading up to the first attack and each of the 4 weeks after the last attack. The country-round pairs that are dropped when we go to from the two-to the 4-week bandwidth are: the Czech Republic-Round 6, Ireland-Round 8, Poland-Round 5, and Spain-Round 4 (Appendix Table A2). Descriptive statistics for ESS respondents in 4-week bandwidth sample are provided in Panel B of Table 1. The results of regressing respondent characteristics on the post-attack dummy and country-by-round fixed effects are reported in the third column of Table 1, Panel B. They suggest that the pre-versus post-attack samples are generally balanced in the 4-week bandwidth sample, although two differences are statistically significant: experiencing a terror attack is associated with an almost two-year reduction in respondent’s age and a 0.35 increase in years of education.

Specifically, the zero-week indicator in Figs. 2–7 is for interviews that were conducted 0–6 days after the last attack. The one-week indicator is for interviews conducted 7–13 days after the last attack, and so forth. The negative one-week indicator is for interviews conducted 1–7 days before the first attack.

When using an 8-week bandwidth, we do not require that ESS interviews were conducted in each of the 8 weeks leading up to a fatal attack and each of the 8 weeks after an attack. As a consequence, 4 additional country-round pairs are included in the analysis: Hungary-Round 4, Ireland-Round 3, and the United Kingdom-Rounds 1 and 7. Event-study analyses based on an 8-week bandwidth are reported in Appendix Figures A3–A8. The results of these analyses should, however, be viewed with caution because each event-study coefficient is based on different within-country pre-versus post-attack comparisons. Using an 8-week bandwidth, there are small but statistically significant increases in the belief that fewer immigrants from poor countries should be allowed 0, 2 and 3 weeks after an attack (Appendix Figure A4). These estimates range from 0.056 to 0.082 (with p-values of 0.021–0.027). However, 5–7 weeks after an attack, there is a pronounced downward trend in how ESS respondents answered this question, suggesting that any effect of fatal terror attacks on attitudes toward immigrants from poor countries was not only small but impermanent.
respondent’s region. While fatal terror attacks typically receive national and even international attention, press coverage is more intense at the regional and local levels.

To explore the effects of terror attacks on political attitudes and orientation at the regional level, we estimate the following regression model:

\[
y_{icrm} = \pi_0 + \pi_1 \text{Post Attack}_{icrm} + \pi_2 \text{Post Attack}_{icrm} \times \text{Region}_{icrm} + X_{icrm} \beta + \theta_m + \delta_{ic} + \epsilon_{icrm},
\]

where the post-attack indicator is interacted with the variable Region, equal to 1 if the respondent lived in the NUTS-1 region of the country that experienced the attack. In place of the country-by-round fixed effects used in equations (1) and (2), we include region-by-round fixed effects, \(\delta_{ic}\). For this analysis we cluster the standard errors at the region-by-round level.

Estimates of equation (2) based on two- and 4-week bandwidths are
Fig. 4. Event Study Estimates: Fatal Terror Attacks and “Trust in Country’s Parliament”
Notes: Based on individual-level data from the European Social Surveys (ESS). Figure plots coefficient estimates for weeks-since-attack indicators as described in the text, along with 90% confidence intervals. The sample includes respondents interviewed 1–28 days before the first attack during the survey period and respondents interviewed 0–27 days after the last attack. Regressions include country-by-round and month-of-year fixed effects, and control for respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.

Notes: Based on individual-level data from the European Social Surveys (ESS). Figure plots coefficient estimates for weeks-since-attack indicators as described in the text, along with 90% confidence intervals. The sample includes respondents interviewed 1–28 days before the first attack during the survey period and respondents interviewed 0–27 days after the last attack. Regressions include country-by-round and month-of-year fixed effects, and control for respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.
Fig. 6. Event Study Estimates: Fatal Terror Attacks and “Trust in European Parliament”
Notes: Based on individual-level data from the European Social Surveys (ESS). Figure plots coefficient estimates for weeks-since-attack indicators as described in the text, along with 90% confidence intervals. The sample includes respondents interviewed 1–28 days before the first attack during the survey period and respondents interviewed 0–27 days after the last attack. Regressions include country-by-round and month-of-year fixed effects, and control for respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.

Fig. 7. Event Study Estimates: Fatal Terror Attacks and Political Orientation
Notes: Based on individual-level data from the European Social Surveys (ESS). Figure plots coefficient estimates for weeks-since-attack indicators as described in the text, along with 90% confidence intervals. The sample includes respondents interviewed 1–28 days before the first attack during the survey period and respondents interviewed 0–27 days after the last attack. Regressions include country-by-round and month-of-year fixed effects, and control for respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.
reported in Tables 3 and 4, respectively. They provide evidence that terror attacks can affect political attitudes among residents of the region in which they occur. The direction of these estimated effects is, however, not consistent with the idea that the recent surge in terrorism has weakened faith in government and parliamentary institutions.

Using a two-week bandwidth, experiencing a fatal terror attack is associated with a 0.322 increase ($\hat{\pi}_{21}$) in whether residents in the affected region believed that immigrants made their country a better place (Table 3). Although the estimate of $\pi_2$ appears to be statistically significant, the null ($H_0: \pi_2 = 0$) cannot be rejected if we adopt the Benjamini–Hochberg procedure for the false discovery rate (Benjamini and Hochberg 1995). Likewise, experiencing a fatal terror attack is associated with a 0.109 increase ($\hat{x}_{12}$) in whether respondents believed that there should be fewer immigrants from poorer countries, but the null ($H_0: \pi_{22} = 0$) cannot be rejected if we adopt the Benjamini–Hochberg procedure. The remaining estimates of $x_{1}$ and $x_{2}$ reported in Table 3 are statistically insignificant at conventional levels.

When we adopt a 4-week bandwidth, there is evidence that terror attacks led to sizable rally-around-the-flag effects in the affected region (i.e., the region in which the attack occurred). A fatal terror attack is associated with a 0.462 increase in trust in the parliament ($\hat{x}_{11}$) and a 0.470 increase in satisfaction with the national government ($\hat{x}_{21}$) in the affected region (Table 4). The former estimate represents a 10 percent increase relative to the sample mean (4.530),
6. Separate estimates by country-round pair

The estimates reported thus far have been based on a pooled sample, potentially masking important heterogeneity. For instance, 5 of the attacks in our 4-week bandwidth sample involved only a single fatality, while 4 were mass-casualty events that garnered global attention; four of the attacks were perpetrated by Jihadi-inspired extremists, while at least 5 involved more domestic political conflicts (Appendix Table A2).

While the attacks were perpetrated by Jihadi-inspired extremists, while at least 5 were mass-casualty events that garnered global attention, four of them were high-profile terror attacks. The relevant estimates of $\pi_2$ are statistically significant and sizeable. ETA planted a bomb in the Terminal 4 parking area of the Madrid airport when Round 3 of the ESS was in the field, killing two bystanders and wounding 12. This attack does not seem to have affected trust in parliament or satisfaction with the national government, but it is associated with a 0.159 increase in the belief that fewer immigrants from poorer countries should be allowed, which is 6 percent of the mean response (2.50).

6.1. Terror attacks in Spain

Two small-scale terror attacks were carried out by the Basque Fatherland and Freedom (ETA) movement when Round 1 of the ESS was in the field. In the first attack occurred on December 17, 2002, and the second occurred on February 8, 2003. These attacks, each of which resulted in the death of a police officer, seem to have reduced trust in the parliament and satisfaction with the national government among Spanish ESS participants. The relevant estimates of $\pi_2$ are statistically significant and sizeable. ETA planted a bomb in the Terminal 4 parking area of the Madrid airport when Round 3 of the ESS was in the field, killing two bystanders and wounding 12. This attack does not seem to have affected trust in parliament or satisfaction with the national government, but it is associated with a 0.159 increase in the belief that fewer immigrants from poorer countries should be allowed, which is 6 percent of the mean response (2.50).

6.2. Terror attacks in France

France experienced a series of terror attacks between December 20, 2014 and January 9, 2015, when Round 7 of the ESS was in the field. Among them, was the attack on the offices of the satirical weekly magazine Charlie Hebdo, in which 12 people were killed and 11 wounded. Trust in parliament increased by 0.707 in the post-attack period as compared to the pre-attack period; similarly, there was a 0.828 increase in satisfaction with the national government. Consistent with the results of Silva (2018), who also used data from the ESS to examine the effects of the Charlie Hebdo shootings, we find little evidence that the attack affected French attitudes towards immigrants.

The attack on French soil during Round 8 was small-scale (only one person was killed) and the perpetrator is still unknown. We find no evidence that it appreciably altered political attitudes. By contrast, the mass shooting by jihadi-inspired extremists at the Strasbourg Christmas market on December 11, 2018 (while in Round 9 of the ESS was in the field) resulted in 5 deaths, received a great deal of press coverage, and anecdotally caused great anxiety among the French (Rubin and Breeden 2018). It does not appear to have affected attitudes towards immigrants or the national government, but there was a post-attack increase of 0.504 in left-right political orientation.

6.3. Terror attacks in the United Kingdom

Two small-scale attacks perpetrated by the New Irish Republican Army (IRA) took place while Round 6 of the ESS was in the field. The IRA carried out another small-scale attack while Round 8 was in the field, and the Irish National Liberation Army (INLA) carried out a fourth small-scale attack while Round 9 was in the field. There is no evidence of post-attack changes in political attitudes or orientation.

6.4. Terror attacks in the Netherlands

On November 2, 2004, the filmmaker Theo van Gogh was shot and decapitated by a member of a jihadist group while Round 2 of the ESS was in the field. This attack received worldwide attention and inspired a series of attacks on mosques in the Netherlands (Finseraas et al., 2011). We also have responses from Round 4 of the ESS before and after a car attack on the Dutch royal family. This latter attack occurred on May 1, 2009 and killed 5 festival-goers. The motives of the perpetrator are still unknown.

Consistent with the results of Finseraas et al. (2011), there is a statistically significant decrease among Dutch respondents in the belief that immigrants make the country better after the murder of Theo van Gogh. Specifically, our estimate of $\pi_1$ is $-0.398$, or 8 percent of the mean (4.974). The van Gogh murder also appears to have increased trust in the Dutch Parliament as well as trust in the European Parliament, a pattern of results that is suggestive of a rally-around-the-flag effect. There is no evidence that the May 1, 2009 attack affected political attitudes.

Appendix Table A2 provides additional details on the heterogeneity of responses to terror attacks across countries and rounds. The estimates reported in Table 5 are based on 4-week bandwidths. Using a two-week bandwidth, the May 1, 2009 attack is associated with an increase in the belief that immigrants make country better.

Consistent with the results of Finsera et al. (2011), we find evidence that attitudes towards immigrants among Dutch ESS respondents hardened after the murder of Theo van Gogh by jihadi-inspired extremists. By contrast, other high-profile terror attacks do not seem to have appreciably affected attitudes towards immigrants, although there was a substantial increase in how much trust French respondents had in their parliament after the Charlie Hebdo shootings. While focusing on specific terror attacks allows us to compare our estimates to those of previous studies, it is difficult to draw firm conclusions from our country-by-round analysis. Neither high-profile attacks committed by jihadi-inspired extremists nor small-scale attacks committed by ETA or the IRA appear to have elicited systematic responses from ESS respondents, a pattern of results that clearly illustrates the value of analyzing pre- and post-survey data from as many terror attacks as possible.

There is an ongoing debate as to the effectiveness of terrorism. Studies including those by Berrebi and Klor (2008), Gould and Klor (2010), Montalto (2011, 2012), and Akaya et al. (2020) provide evidence that terror attacks can influence political opinions and alter choices at the ballot box. Other researchers, however, have concluded that terrorism has little, if any, impact on political attitudes and election outcomes (Abrahams 2006, 2007, 2012; Lago and Montero 2006; Arvanitidis et al., 2016; Balseels and Torrats-Espinosa 2018; Silva 2018). We view our results, described above, as directly contributing to this debate. Although popular support in Europe for right-wing anti-immigration parties has undoubtedly been on the rise (Holleran 2018; Roth 2018; Anderson and Kwai, 2022), our results are not consistent with the hypothesis that terror attacks systematically influence political orientation and attitudes towards immigrants, at least in the short run.

**Individual controls**
- No

*Statistically significant at 10% level; ** at 5% level; *** at 1% level.

Notes: Based on individual-level data from the European Social Surveys (ESS). Each coefficient estimate (and its standard error, which is reported in parentheses) is from a separate OLS regression where the dependent variable is equal to respondent i’s level of agreement with the relevant question. Standard errors are clustered at the country-round level. Sample sizes are reported in brackets. The two-week bandwidth sample includes respondents interviewed 1–14 days before the first attack during the survey period and those interviewed 0–13 days after the last attack. The four-week bandwidth sample includes respondents interviewed 1–28 days before the first attack during the survey period and those interviewed 0–27 days after the last attack. Post attack is equal to 1 if the respondent was interviewed on or after the day of the attack (and is equal to 0 otherwise). Regressions include country-by-round fixed effects and month-of-year fixed effects.

Notes: Based on individual-level data from the European Social Surveys (ESS). The table reports the coefficient estimate for $\pi_2$ from Equation (3). Each estimate (and its standard error, which is reported in parentheses) is from a separate OLS regression where the dependent variable is equal to respondent $i$’s level of agreement with the relevant question, limiting the sample to respondents from the indicated country-round pair. Standard errors are corrected for heteroskedasticity. The sample includes respondents interviewed 1–28 days before the first attack during the survey period and those interviewed 0–27 days after the last attack. Regressions include region fixed effects, respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.
Fig. A1. Pre- and Post-Attack Interview Counts for Country-Round Pairs (4-Week Bandwidth Sample)
Notes: Figures show interview counts by weeks since the first/last attack. The zero-week indicator is for interviews that were conducted 0–6 days after the last attack. The one-week indicator is for interviews conducted 7–13 days after the last attack, and so forth. Interview counts are shown for the 12 country-round pairs comprising our four-week bandwidth sample.
Fig. A1. (continued).

Notes: Figures show interview counts by weeks since the first/last attack. The zero-week indicator is for interviews that were conducted 0-6 days after the last attack. The one-week indicator is for interviews conducted 7-13 days after the last attack, and so forth. Interview counts are shown for the 12 country-round pairs comprising our four-week bandwidth sample.
Fig. A2. Pre- and Post-Attack Interview Counts for Country-Round Pairs (Two-Week Bandwidth Sample)

Notes: Figures show interview counts by weeks since the first/last attack. The zero-week indicator is for interviews that were conducted 0-6 days after the last attack. The one-week indicator is for interviews conducted 7-13 days after the last attack, and so forth. Interview counts are shown for the 4 country-round pairs that are included in the two-week bandwidth sample but not the four-week bandwidth sample.
Fig. A3. Event Study Estimates: Fatal Terror Attacks and “Immigrants Make Country Better Place to Live” (8-Week Bandwidth)
Notes: Based on individual-level data from the European Social Surveys (ESS). Figure plots the coefficient estimates for the weeks-since-attack indicators as described in the text, along with 90% confidence intervals. The sample includes respondents interviewed 1-56 days before the first attack during the survey period and those interviewed 0-55 days after the last attack. Regressions include country-by-round and month-of-year fixed effects, respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.

Fig. A4. Event Study Estimates: Fatal Terror Attacks and “Allow Fewer Immigrants from Poorer Countries” (8-Week Bandwidth)
Notes: Based on individual-level data from the European Social Surveys (ESS). Figure plots the coefficient estimates for the weeks-since-attack indicators as described in the text, along with 90% confidence intervals. The sample includes respondents interviewed 1-56 days before the first attack during the survey period and those interviewed 0-55 days after the last attack. Regressions include country-by-round and month-of-year fixed effects, respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.
Fig. A5. Event Study Estimates: Fatal Terror Attacks and “Trust in Country’s Parliament” (8-Week Bandwidth)
Notes: Based on individual-level data from the European Social Surveys (ESS). Figure plots the coefficient estimates for the weeks-since-attack indicators as described in the text, along with 90% confidence intervals. The sample includes respondents interviewed 1–56 days before the first attack during the survey period and those interviewed 0–55 days after the last attack. Regressions include country-by-round and month-of-year fixed effects, respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.

Fig. A6. Event Study Estimates: Fatal Terror Attacks and “How Satisfied with National Government” (8-Week Bandwidth)
Notes: Based on individual-level data from the European Social Surveys (ESS). Figure plots the coefficient estimates for the weeks-since-attack indicators as described in the text, along with 90% confidence intervals. The sample includes respondents interviewed 1–56 days before the first attack during the survey period and those interviewed 0–55 days after the last attack. Regressions include country-by-round and month-of-year fixed effects, respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.
Fig. A7. Event Study Estimates: Fatal Terror Attacks and “Trust in European Parliament” (8-Week Bandwidth)
Notes: Based on individual-level data from the European Social Surveys (ESS). Figure plots the coefficient estimates for the weeks-since-attack indicators as described in the text, along with 90% confidence intervals. The sample includes respondents interviewed 1–56 days before the first attack during the survey period and those interviewed 0–55 days after the last attack. Regressions include country-by-round and month-of-year fixed effects, respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.

Fig. A8. Event Study Estimates: Fatal Terror Attacks and Political Orientation (8-Week Bandwidth)
Notes: Based on individual-level data from the European Social Surveys (ESS). Figure plots the coefficient estimates for the weeks-since-attack indicators as described in the text, along with 90% confidence intervals. The sample includes respondents interviewed 1–56 days before the first attack during the survey period and those interviewed 0–55 days after the last attack. Regressions include country-by-round and month-of-year fixed effects, respondents’ age, gender, years education, an indicator for living in an urban area, an indicator for minority status, and an indicator for respondent coping at current income level.
Appendix B. Text of EES questions as they appear in survey

B43 CARD 18 Is [country] made a worse or a better place to live by people coming to live here from other countries? Please use this card.

<table>
<thead>
<tr>
<th>Worse place to live</th>
<th>Better place to live</th>
<th>(Refusal)</th>
<th>(Don't know)</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>01</td>
<td>02</td>
<td>03</td>
</tr>
<tr>
<td>04</td>
<td>05</td>
<td>06</td>
<td>07</td>
</tr>
<tr>
<td>08</td>
<td>09</td>
<td>10</td>
<td>77</td>
</tr>

Now some questions about people from other countries coming to live in [country].

B38 CARD 15 Now, using this card, to what extent do you think [country] should allow people of the same race or ethnic group as most [country]'s people to come and live here?

| Allow many to come and live here | 1 |
| Allow some                      | 2 |
| Allow a few                     | 3 |
| Allow none                      | 4 |
| (Refusal)                       | 7 |
| (Don't know)                    | 8 |

B40 STILL CARD 15 How about people from the poorer countries outside Europe? Use the same card.

| Allow many to come and live here | 1 |
| Allow some                      | 2 |
| Allow a few                     | 3 |
| Allow none                      | 4 |
| (Refusal)                       | 7 |
| (Don't know)                    | 8 |
