Abstract:

Nuclear magnetic resonance measurements have been made on the Li7 spin system-in large single crystals of LiN₂H₅SO₄. The Li7 relaxation time, T₁, has been measured at 14 MHz for temperatures from 75 °K to 373 °K, and the ND₂ deuteron T₁ for temperatures from 100°K to 250°K. The activation energy for the observed relaxation in both the Li7 and ND₂ deuteron relaxation for low temperatures is $0.20 \pm .02$ eV, as previously reported for NH₃ and ND₃ groups in the respective crystals. The Li7 and low temperature ND_g deuteron relaxation accordingly results from hindered rotation of these groups, and is shown to be dipolar in all cases. The observed minimum T₁'s occur at 185°K and are 2.2 sec. in LiN₂D₅SO₄, 0.52 sec. in LiN₂H₅SO₄ and 4.0 sec. for ND₂ deuterons. These data imply that the LiN₂D₅SO₄ crystal was only 80% deuterated. Also measured were the Li7 quadrupolar coupling constant eqQ/h and asymmetry η in LiN₂D₅SO₄. As temperature increases from 75°K to 447°K, eqQ/h decreases from 46.1 to 34.1 kHz and η decreases from 0.69 to 0.46.

Measurements were made of the pyroelectric coefficients in both LiN₂H₅SO₄ and LiN₂D₅SO₄ from 75°X to 150°K. The measured pyroelectric coefficients at 75°K are 11.4 ± 0.3 egs units for LiN₂H₅SO₄ and 7.6 ± 0.1 egs units for LiN₂D₅SO₄. The pyroelectric polarization is shown to be irreversible at 75°K confirming that both substances are not ferroelectric.

The observation of "hysteresis" loops has been shown to be consistent with a saturable dielectric. The model assumed is that of a series of periodically blocked channels along the c-axis. The complex dielectric constant of such a model is calculated and photographs of predicted behavior are shown. The inferred mean extrinsic barrier separation is from 6000 Å to 15,000 Å.

A DIELECTRIC AND NUCLEAR MAGNETIC RESONANCE STUDY OF
LITHIUM HYDRAZINIUM SULFATE AND ITS DEUTERATED ISOMORPH

ACKNOWLEDGEMENTS

The author wishes to thank the National Science Foundation and the National Institute of Health for financial assistance and for providing the equipment and material used in this research. To his advisor, Dr. V. Hugo Schmidt, he owes a great debt for continuous encouragement, understanding, and helpful discussion. To Drs. F. L. Howell and R. R. Knispel he is grateful for helpful discussions, timely preprints, inheritance of equipment, and priceless friendship; even more necessary during the production of a thesis. To Dr. J. E. Drumheller he is grateful for helpful discussions and encouragement given during the terminal stages of the thesis in his advisor's sabbatical absence. He thanks Drs. J. A. Ball and J. B. Hermanson for many helpful suggestions. To Fred Blankenburg he extends thanks for generous assistance with the electronic apparatus. He thanks Cecil Badgley for assistance with the machine work. Dr. Emerson of the Chemistry Department and Drs. J. Hanton and R. Stabb have been most willing to provide assistance and loan of facilities of the Electrical Engineering Department. To Mrs. Barbara Anderson he extends his appreciation for her ability to decipher handwritten chicken scratchings to the typewritten page. Miss Donna Miller he thanks for assistance with typing, English, and constant encouragement.

ABSTRACT

Nuclear magnetic resonance measurements have been made on the Li^7 spin system in large single crystals of $\text{LiN}_2\text{H}_5\text{SO}_4$. The Li^7 relaxation time, T_1 , has been measured at 14 MHz for temperatures from 75°K to 373°K , and the ND_2 deuteron T_1 for temperatures from 100°K to 250°K . The activation energy for the observed relaxation in both the Li^7 and ND_2 deuteron relaxation for low temperatures is $0.20 \pm .02$ eV, as previously reported for NH_3 and ND_3 groups in the respective crystals. The Li^7 and low temperature ND_2 deuteron relaxation accordingly results from hindered rotation of these groups, and is shown to be dipolar in all cases. The observed minimum T_1 's occur at 185°K and are 2.2 sec. in $\text{LiN}_2\text{D}_5\text{SO}_4$, 0.52 sec. in $\text{LiN}_2\text{H}_5\text{SO}_4$ and 4.0 sec. for ND_2 deuterons. These data imply that the $\text{LiN}_2\text{D}_5\text{SO}_4$ crystal was only 80% deuterated. Also measured were the Li^7 quadrupolar coupling constant eqQ/h and asymmetry η in $\text{LiN}_2\text{D}_5\text{SO}_4$. As temperature increases from 75°K to 447°K , eqQ/h decreases from 46.1 to 34.1 kHz and η decreases from 0.69 to 0.46.

Measurements were made of the pyroelectric coefficients in both $\text{LiN}_2\text{H}_5\text{SO}_4$ and $\text{LiN}_2\text{D}_5\text{SO}_4$ from 75°K to 150°K . The measured pyroelectric coefficients at 75°K are 11.4 ± 0.3 egs units for $\text{LiN}_2\text{H}_5\text{SO}_4$ and 7.6 ± 0.1 egs units for $\text{LiN}_2\text{D}_5\text{SO}_4$. The pyroelectric polarization is shown to be irreversible at 75°K confirming that both substances are not ferroelectric.

The observation of "hysteresis" loops has been shown to be consistent with a saturable dielectric. The model assumed is that of a series of periodically blocked channels along the c-axis. The complex dielectric constant of such a model is calculated and photographs of predicted behavior are shown. The inferred mean extrinsic barrier separation is from 6000 Å to 15,000 Å.

Chapter I

INTRODUCTION

The compound lithium hydrazinium sulfate ($\text{LiN}_2\text{H}_5\text{SO}_4$), hereafter denoted LiHzS, was first prepared by Sommer and Weise¹ in 1916. The recent interest in both LiHzS and its deuterated isomorph $\text{LiN}_2\text{D}_5\text{SO}_4$ (LiDzS) was kindled by Pepinsky, et al.,² in 1958 when they reported their observation of what appeared to be ferroelectric hysteresis loops in LiHzS over the temperature range from -15°C to above 80°C . This placed LiHzS in a fairly small group of solids which are classed as hydrogen-bonded ferroelectrics. Generally, hydrogen-bonded ferroelectrics are studied as a means of gaining insight into the mechanics of hydrogen-bonding and the nature of the ferroelectric phase transition.

A good example of such a study has been the continued effort on KH_2PO_4 and KD_2PO_4 begun in about 1955 by Uehling and co-workers at the University of Washington^{3,4,5} and continued today in several laboratories throughout the world. These studies have provided us with measurements of deuteron migration rates between hydrogen bonds and between the two stable deuteron locations within each hydrogen bond. The intrabond motion is related to the dielectric behavior and the sharpness of the phase transition while the interbond motion is responsible for the electrical conductivity.

"Ferroelectric" LiHzS and LiDzS have been the subjects of several

recent studies.⁶⁻²⁰ There have been several nuclear magnetic resonance (NMR) studies of the proton line width in LiHzS culminating in the rather extensive studies of the proton and Li⁷ line width and spin-lattice relaxation done by Cuthbert and Petch⁹ and the later studies done by MacClement, Pintar, and Petch¹⁰ and by Knispel and Petch.¹¹ These workers all found evidence of molecular reorientation within the hydrazinium (N₂H₅⁺) ion, but the assignment of the appropriate relaxation parameters could only be made by inference from similar phenomena in other crystals. This uncertainty was lifted by Howell and Schmidt^{12,13} who completed a deuteron magnetic resonance study of LiDzS and concluded that the ND₂ and ND₃ groups rotate with an activation energy of 0.50 eV and 0.20 eV respectively. The high degree of correlation between these hindered rotation data is shown in Table I-1, taken from reference by Knispel and Petch.¹¹ In this work the electric field gradient tensor for the Li⁷ nucleus in LiDzS has been measured and the Li⁷ spin-lattice relaxation time has been measured. These NMR studies, along with the present work, are further discussed in Chapters II and IV.

The structure of LiHzS was obtained from a series of x-ray and neutron diffraction studies made from 1963 to 1967.^{13,14,15} These studies revealed a structure consisting of channels formed by interconnected LiO₄ groups and SO₄ groups winding spirally along the c-axis (Fig.I-1a). Within these channels are chains of hydrazinium

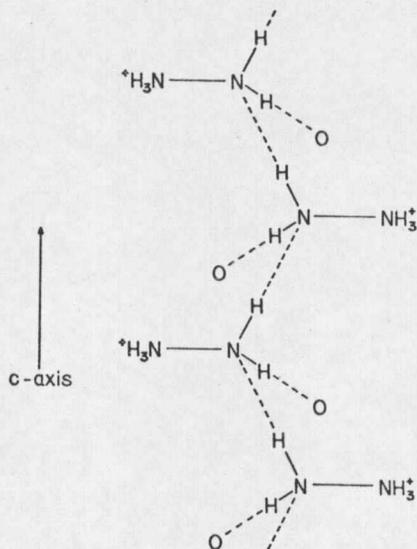

Figure I - 1b View of Hydrazine Chain Along c-Axis.

($N_2H_5^+$) ions which are composed of NH_2 and NH_3^+ groups (Fig. I-1b). The hydrogen locations were found by neutron diffraction studies, while the NMR investigations showed that both the NH_2 and NH_3^+ groups undergo hindered rotations. In 1969 Ross,¹⁶ at Brookhaven, did a neutron diffraction study on $LiDzS$ revealing a structure quite similar to $LiHzS$.

Of particular interest have been the studies of the dielectric properties and electrical conductivity. After Pepinsky's original paper, Vanderkooy, Cuthbert, and Petch¹⁹ measured the conductivity of $LiHzS$ and found a high (about the factor of 200) anisotropy in the conductivity and showed that the high conductivity along the c-axis was protonic in nature. Howell, Schmidt, and Knispel¹⁸ found qualitatively similar behavior for the conductivity in $LiDzS$.

A surprising feature of the conductivity data is that for temperatures above about $100^\circ C$ the a- and b- axis conductivities rise more rapidly with increasing temperature, approaching the c-axis value at about the temperature at which the crystal decomposes (Fig. I-2).

Of special interest in this study is the strong possibility that $LiHzS$ and/or $LiDzS$ are not ferroelectric but that the so-called hysteresis loops are the result of a non-linear dielectric. That is, the dielectric constant K is in fact not a constant but a limiting function of applied field.
